

Head width is measured at the widest transverse point of the head, recomputed per specimen

A The anatomical definition encoded in the model

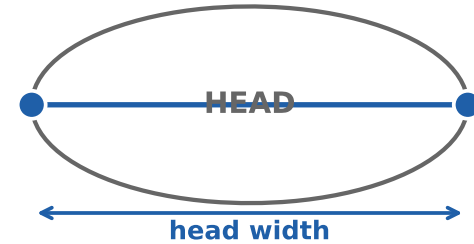

B How the measurement is defined

head part
(`b\_h` skinning group)

dorsal view

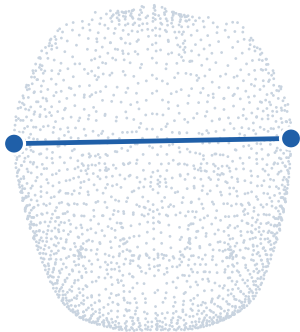

extreme points along the head's own lateral axis,
after rigid alignment of the head to the template frame

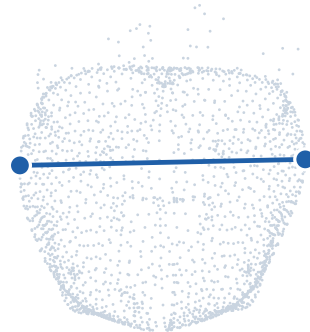

not a fixed vertex pair — recomputed per specimen,
so it tracks the true widest point as head shape changes

C Where the measurement lands on registered real specimens (frontal view, head frame)

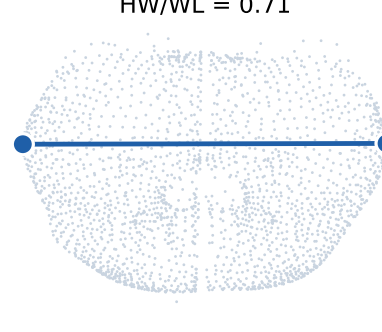

Anochetus horridus
HW/WL = 0.37

Aphaenogaster trinacriae
HW/WL = 0.56

Anochetus sp.
HW/WL = 0.71

Acromyrmex echinator
HW/WL = 1.28
